

The "Stereo-Plus" System

Finding a source of signal for the center-channel speaker when its use is desired because of wide speaker spacing is simplified considerably by the method proposed by these authors.

RICHARD SHOTTENFELD* and WALTER STAUDT*

TO ACHIEVE WIDEST ANGLE stereo sound, the separation between speakers should be made as great as possible. As the spacing between two stereo speakers is increased, the apparent sound source becomes broader. Ultimately, a spacing is reached beyond which the width no longer increases. Instead, the single apparent sound source divides into two—one localized at each of the speakers. The central area between the two speakers tends to become a zone of silence, sometimes referred to as the "hole in the middle."

Prolonged listening to excessively spaced speakers is tiring because attention repeatedly swings from speaker to speaker. Where decor, room size, or the desire for a relatively broad source of sound require very wide speaker spacing, a third, centrally located, speaker system can recreate the sounds that originated at the center of the stage. To do this the center channel speaker *must* be driven by a signal which is proportional to the *sum* of Channel A *plus* Channel B.

One system that has been proposed, and currently is in limited use, is shown in Fig. 1. This takes signals from Channel A and Channel B speaker terminals and combines them in a resistive summing network.¹ The resultant *sum* signal voltage must then be applied to a *third* power amplifier that drives the center-channel speaker. This system is effective, but the requirement for a third power

Fig. 2. Center-channel signal resulting from direct connection between corresponding impedance taps. With identical amplifiers, the signal to the center speaker is zero on in-phase or monophonic program material.

amplifier channel is a serious disadvantage.

Another system, intended to avoid the need for a third amplifier channel and shown in Fig. 3, connects the center-channel speaker between speaker terminals of the same impedance of Channels A and B.¹ A speaker so connected responds to the *difference* between Channel A and Channel B signals. Monophonic programs and the portions of stereo programs that originated at center stage produce identical signals at Channel A and Channel B output. The difference between identical signals is zero; therefore the center speaker will not re-create center-stage sounds, and will produce no sound from monophonic signals.

Phase-Shift System

In an attempt to avoid the shortcomings of the *difference* signal of Fig. 2, or the additional amplifier required with the *sum* signal of Fig. 1, a third system has been suggested.² This system, shown in Fig. 3, uses an all-pass network in the output of one channel to shift the frequencies at the center of the audio spectrum by 90 deg. The intent is to avoid zero output from the center speaker when identical signals appear at the output of both channels. Aside from the practical problems of constructing such a network, the effectiveness of a 90-deg. phase shift, limited to the center of the audio spectrum, is questionable.

The authors have also investigated a number of alternative systems for di-

Fig. 3. Center-channel signal derived from 90-deg. phase-shift network to avoid zero output on monophonic signals.

rectly driving the center-channel speaker with a signal which is proportional to the *sum* of Channel A *plus* Channel B. The basic requirement is for two equal voltages, one from Channel A and the other from Channel B, which can be connected series-aiding to the center speaker.

The most obvious method, which can be used with any existing amplifier, requires a 1:1 ratio transformer for inverting the phase of the output of one

*Paul W. Klipsch, "Three-channel stereo playback of two tracks derived from three microphones." *IRE Trans PGA*, March-April, 1959.

Fig. 1. Center-channel sum-signal circuit requiring a third power amplifier.

"STEREO-PLUS" SYSTEM

(from page 23)

channel as shown in *Fig. 4*. Such a transformer must be able to handle the full power output of one channel, and must be of high efficiency to conserve valuable audio power. The transformer should also be bifilar wound to introduce the least possible degradation of the high-frequency power response. Since com-

mercially available units meeting these requirements could not be located, special transformers were constructed. The size and cost of each proved to be substantially equal to the output transformers used in the amplifier.

Another satisfactory method, but requiring a special amplifier or modifica-

Record Playback
STEREO TAPE DECK
Professional quality at a popular price . . .
only **\$129.95**

A supreme achievement in tape deck design and performance, the ARKAY/HARTING records your favorite music with the same superb performance of tape recorders costing many times more. No other tape deck—tearless performance, the ARKAY/HARTING records your favorite music with the same superb performance of tape recorders costing many times more. No other tape deck—regardless of price—offers so many important features. Here's just a few:

- Dual-track combination head for two speeds
- 30-16,000 cps ± 2 db.
- Flutter and wow: $\frac{1}{4}$ of 1%
- Five-button operation
- —55 db. S/N
- All-metal tape fingers, drop-in loading
- All-metal tape guards
- Large ($\frac{1}{2}$ " diam.) capstan
- Size: 12 $\frac{3}{4}$ " x 14 $\frac{1}{2}$ " x 6 $\frac{1}{4}$ "

Available soon, new ARKAY stereo record and playback PRE-AMPLIFIER in kit of pre-wired form, specially designed for the ARKAY/HARTING.

tion of an existing amplifier, uses an electronic phase inverter in one channel only, to reverse the output phase as shown in Fig. 5. The output of one channel is then in opposite phase to the other, over the entire audio spectrum. A speaker connected, between channels, to taps of the same impedance receives a signal which is proportional to the sum of Channel A plus Channel B.

A Simpler Solution

The "Stereo-Plus" System is an ideal solution to the problem of providing sum signal drive to the center-channel speaker system. It fulfills all of the required conditions and has none of the disadvantages inherent in the other systems described. Only a simple modification of the output circuits of a conventional stereo amplifier is required to obtain the advantages of the "Stereo-Plus" System. This system and its underlying principles are the subject of a U.S. patent application.

Basically, the modification involves grounding an existing tap of the output winding on one channel of a stereo amplifier, instead of one end as in usual practice. This makes voltages of opposite phase available from that winding. The other channel of the stereo amplifier is not changed. The other channel or the stereo amplifier is not changed.

The series-aiding connection of two equal voltages, one from Channel A and the other from Channel B, required for

Fig. 5. Additional electronic phase inversion will supply center-channel signal, but requires amplifier complication.

Stuzzi
MAGNETTE
transistorized
tape recorder
with professional
broadcast quality!

Professional performance packed into a mere eight pounds! Hand-crafted in Vienna to the highest Continental standards, it's the ideal traveling companion for dictation, conference recording, interviews and recording fine music to broadcast standards. Up to two hours interviews and recording fine music to broadcast standards. Up to two hours on each reel!

Fully transistorized, (seven transistors + 2 diodes) the STUZZI Magnette will operate up to 100 hours on 4 standard flashlight batteries. Vibration-proof, it will operate in any position . . . on land, sea and air. Wow and flutter to professional minimums. New feather-touch push button controls for whisper-quiet performance plus these features:

- Dual Track—Dual Speed $3\frac{3}{4}$ -1 $\frac{1}{2}$ ips.
- VU Level Magic-Eye Modulation.
- Separate motors for fast wind and capstan drive.
- Battery Life Indicators.
- Tapes can be replayed on all recorders.
- Doubles as small portable PA system.
- An engineering triumph!

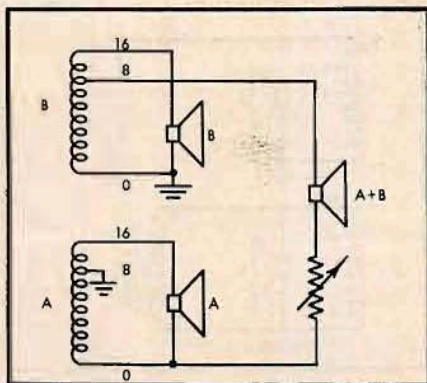

Fig. 6. Method of obtaining the center-channel sum signal by modifying output circuitry of one amplifier.

the sum signal, can be traced in Fig. 6 as follows. The path is from the end of the winding which was originally grounded in the converted channel, through the common ground connection, to the same impedance tap on the unconverted channel. A center-channel speaker connected as shown in Fig. 6 will respond to the sum of Channel A plus Channel B and therefore will reproduce center-stage sounds and monophonic signals.

In amplifiers with 4-ohm taps, advantage can be taken of the fact that the 4-ohm taps are the electrical center taps of 16-ohm windings. With the 4-ohm tap of both channels as the grounded point, equal voltages of either polarity are available from both channels. The modification in both channels is made by grounding the 4-ohm tap on each. In this arrangement both channels remain identical. Figure 7 shows how these voltages can be arranged to feed a sum signal to the center-channel speaker.

Moving the ground from one end of the secondary to a tap reduces the amount of feedback voltage. The feedback network values must be adjusted to restore the feedback to its original value. In any amplifier, changing the point from which the feedback is taken, may adversely affect the stability of the amplifier. After making the feedback change, the amplifier should be tested for stability and corrections made if needed. AE

Fig. 7. Grounding the 4-ohm taps of both amplifiers provides a center-channel sum signal and makes both amplifiers identical.
