+5 to -15 Volts DC Converter

National Semiconductor Linear Brief 18

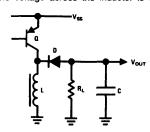

INTRODUCTION

It is frequently necessary to convert a DC voltage to another higher or lower DC-voltage while maximizing efficiency. Conventional switching regulators are capable of converting from a high input DC voltage to a lower output voltage and satisfying the efficiency criteria. The problem is a little more troublesome if a higher output voltage than the input voltage is desired. Particularly, generating DC voltage with opposite polarity to the input voltage usually involves a complicated design.

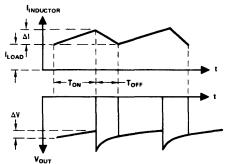

This brief demonstrates the use of the switching regulator idea for a +5 volts to -15 volts converter. The converter has an application as a power supply for MOS memories in a logic system where only +5 volts is available. However, the principle used can be amplied for almost any input output combination.

OPERATION

The method by which the regulator generates the opposite polarity is explained in *Figure 1*. The transistor Q is turned ON and OFF with a given duty cycle. If the base drive is sufficient the voltage across the inductor is equal to the

TL/H/8467-1

TI /H/8467~2

FIGURE 1. Switching Circuit for Voltage Conversion supply voltage minus V_{SAT} . The current change in the inductor is given by:

$$\Delta I = \frac{V_{SS} - V_{SAT}}{L} \times T_{ON} \approx \frac{V_{SS}}{L} T_{ON}$$
 (1)

Turning OFF the transistor the inductor current has a path through the catch diode and this in turn builds up a negative voltage across $R_{\rm L}$.

The figure also shows the current and voltage levels versus time. A capacitor in parallel to the resistor will prevent the voltage from dropping to zero during the transistor ON time. Assuming a large capacitor, we can also write the current change as:

$$\Delta I = \frac{V_{OUT} - V_{D}}{L} \times T_{OFF} \approx \frac{V_{OUT}}{L} \times T_{OFF} \tag{2}$$

In order to get a general idea of the operation for certain input output conditions, we will develop a set of equations. During the transistor ON time, energy is loaded into the inductor. In the same time interval, the capacitor is drained

due to the load resistor R_L. Drop in capacitor voltage:

$$\Delta V = \frac{I_{LOAD} \times T_{ON}}{C}$$
 (3)

During the T_{OFF} time the stored energy in the inductor is transferred to the load and capacitor. A rough estimate of T_{OFF} can be expressed as:

$$T_{OFF} = \frac{V_{SS}}{V_{OUT}} \times T_{ON}$$
 (4)

The capacitor voltage will be restored with a average current given by:

$$I_{C} = \frac{\Delta V \times C}{T_{OFF}} = \frac{I_{LOAD} \times V_{OUT}}{V_{SS}}$$
 (5)

The total inductor current during the OFF time can be written as:

$$I_{INDUCTOR} = I_{LOAD} + I_{C}$$
 (6)

Inspecting Figure 1. We find:

$$I_{C} = \frac{\Delta I}{2} = \frac{V_{SS} \times T_{ON}}{2 \times L} \tag{7}$$

which yields:

$$T_{ON} = \frac{2 \times L \times I_{LOAD} \times V_{OUT}}{V_{SS}^2}$$
 (8)

Taking into account that the efficiency is in the order of 75% the final expression is:

$$T_{ON} = \frac{1.5 \times L \times I_{LOAD} \times V_{OUT}}{V_{SS}^2}$$
 (9)

The above equations will be applied to the regulator shown at Figure 2. The regulator must deliver - 15 volts at 200 mA from a + 5 volt supply. Using a 1 mH inductor the T_{ON} time for Q_2 is 0.18 ms from equation 9. T_{OFF} is 60 μs from equation 4 and the oscillator frequency to:

$$F = \frac{1}{T_{ON} + T_{OFF}} \approx 4 \text{ kHz}$$

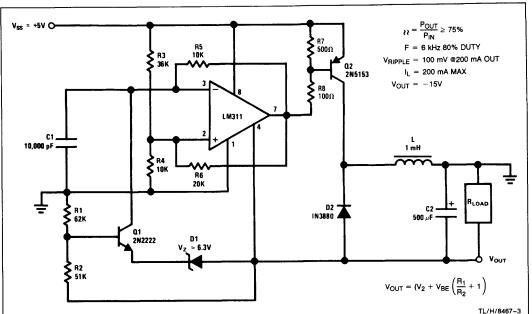

FIGURE 2. Switching Regulator for Voltage Conversion

The LM311 performs like a free running multivibrator with high duty cycle. The IC is designed to operate from a standard single 5 volt supply and has a high output current capability for driving the switching transistor Q_2 . The duty cycle is given by the voltage divider R_3 and R_4 and the frequency of C_1 in conjunction with R_5 .

By setting the duty cycle higher than first calculated, the output voltage will tend to increase above the desired output voltage of 15 volts. However, an extra loop performed by Q₁ and the zener diode in conjunction with the resistor network will modify the oscillator duty cycle until the desired output level is obtained.

The output voltage is given by:

$$V_{OUT} = \left(V_Z + V_{BE}\right) \left(\frac{R_1}{R_2} + 1\right)$$

Data and results obtained with the design:

 $V_{IN} = 5 \text{ volts}$ $V_{OUT} = -15 \text{ volts}$ $I_{OUT} = \text{max } 200 \text{ mA}$

Efficiency ≈ 75%

Frequency ≅ 6 kHz 80% duty cycle V_{RIPPLE} ≅ 100 mV @ 200 mA load

Line regulation: $V_{IN} = 5V$ to $10V < 3\% V_{OUT}$

 $I_{LOAD} = 200 \text{ mA}$

Load regulation: $V_{IN} = 5V < 3\% V_{OUT}$

 $I_{LOAD} = 0 - 100 \text{ mA}$
