# Capacitance Measurement by Frequency Shift 

Why, you might ask, should another article be written concerning capacitance measurement when dozens of articles have appeared on this subject in the past? I have reviewed some of them and find that specialized equipment is generally required that may not be available to the average amateur such as a precision calibrated variable capacitor, a grid dip meter, or a capacitance bridge. All techniques required calibrated standards of some sort which usually turn out to be the stumbling block for the average amateur.

What means of calibration is then available to all? The receiver, of course! Every ham has a receiver these days that is calibrated to within 5,2 and frequently 1 kHz . Even most transceivers are accurate to the latter figure. The problem then is how to use this accurate frequency calibration to measure capacitance. The solution is readily

Finished unit.
evident - tune a simple self excited transistor oscillator to the high frequency edge of one of the amateur bands; connect the unknown capacitance across the oscillator circuit and measure the new lower frequency on the receiver. All that remains to be done is to derive the expression for relating the frequency shift to the unknown capacitance.

A basic Hartley oscillator circuit is shown in Fig. 1. According to R. F. Shea, Transistor Circuit Engineering, John Wiley \& Sons, Inc., 1957, the oscillation frequency for a Hartley transistor oscillator is:
(1) $f=$

1
$2 \pi \sqrt{\mathrm{C}\left(\mathrm{L}_{1}+\mathrm{L}_{2}+2 \mathrm{MO}-\left(\mathrm{L}_{1} \mathrm{~L}_{2}-\mathrm{M}^{2}\right)\right.} \mathrm{h} 22 \mathrm{~b}$ hib
which looks somewhat unmanageable. Fortunately, the expression can be greatly simplified. L1 $+\mathrm{L} 2+2 \mathrm{M}$ is nothing more than the total inductance L of the circuit. Let the second term:

$$
\left(\mathrm{L}_{1} \mathrm{~L}_{2}-\mathrm{M}^{2}\right) \frac{\mathrm{h} 22 \mathrm{~b}}{\mathrm{~h} 11 \mathrm{~b}}=\mathrm{A}
$$

then

$$
1
$$

(2) $\mathrm{f}=2 \pi \sqrt{\mathrm{LC}+\mathrm{A}}$

A is a constant involving the inductive terms $\mathrm{L} 1, \mathrm{~L} 2$, \& M as well as the transistor parameters h22b and h11b and Figs. 2 \& 1. If the assumption is made that this term is negligible, then the familiar expression for the resonant frequency of a tuned circuit results.

Suppose we assume that (3) determines the oscillator frequency for the moment. More will be said about the transistor loading factor "A" later.

It can be shown (see Appendix I) that

where $\mathrm{Cx}=$ unknown capacitance
$\mathrm{f} 1=$ basic oscillator frequency in kHz .
$\Delta \mathrm{f}=$ shift in frequency in kHz due to placing unknown capacitor Cx across tuned circuit
$\mathrm{C} 1=$ fixed, known tank circuit capacitance

The $\Delta \mathrm{f}^{2} / \mathrm{f} 1^{2}$ term is very small compared to $2 \Delta \mathrm{f} / \mathrm{f} 1$ and can be neglected for the moment. Equation (4) reduces to:

The significant facts that emerge from this equation are that the unknown capacitance Cx depends only on the shift in frequency $\Delta f$, the basic frequency fl and the tank capacitance $\mathrm{C} 1 . \mathrm{Cx}$ is thus independent of L and other factors. To measure large values of $\mathrm{Cx}, \mathrm{C} 1$ must be large which dictates the use of the lowest frequency amateur band. 80 meters was selected since 160 isn't available on many receivers. Fortunately, 80 meters is also a wide band and contributes to the range of Cx .

Note that the shift in frequency ( $\Delta \mathrm{f}$ ) is much more important in determining Cx than the basic frequency $f 1$. If $f 1$ is off by 1
$\Delta f, k H z \quad C_{x}, p F \quad \Delta f, k H z \quad C_{x}, p F \quad \Delta f, k H z C_{x}, p F \quad \Delta f, k H z C_{x}, p F \quad \Delta f, k H z \quad C_{x}, p F$

Fig. 2. Frequency-shift capacitance equivalents.
kHz , the effect is only 1 kHz in 4000 kHz whereas a 1 kHz change in $\Delta \mathrm{f}$ has a much larger effect since $\Delta \mathrm{f}$ can vary between 0 to 500 kHz . What this means is that the linearity of your receiver dial calibration is more important than the absolute accuracy. Setting the basic oscillator frequency to 4001 instead of 4000 isn't much cause for concern. The shift in frequency is the important parameter.

The accuracy of Cx is dependent on the accuracy of C1. If C1 is accurate to $5 \%$, Cx will be accurate to $5 \%$. If C1 is accurate to $1 / 2 \%, \mathrm{Cx}$ will be likewise. You can buy as much accuracy as you are willing to pay for. $5 \%$ is sufficient for most amateur applications but great accuracy can be achieved inexpensively in several ways, for example, padding up an undersized C1 if there is precision capacitance measuring equipment available. If not, precision capacitances can be purchased from industrial electronic supply houses. It seems hardly worth buying a $5 \%$ unit for 60 cents when a $1 \%$ unit can be obtained for $\$ 1.37$. The Cornell Dubilier type CD19F102F500 capacitor can be obtained from major supply houses. Arco Electronics, Community Drive, Great Neck, N.Y. 11022 is the distributor for El Menco type DM20 capacitors which can be obtained at $1 \%$ or better tolerance on special order.

One nice feature of the CMBFS technique is that the oscillator is not critical. There is no precision or long term stability required. Temperature, voltage changes, etc. will have no appreciable effect. The only stability required is that long enough to last for 15 seconds - the length of time it takes to make a measurement. Inaccuracies are balanced out by adjusting the variable inductance L to produce a 4000 kHz oscillation frequency immediately prior to the capacitance measurement.

Returning to an earlier assumption, the next step is to verify the accuracy of equation (4) with regard to omission of the transistor loading factor " A ". An oscillator, to be described in the next section, was constructed using a C 1 value of 1000 pF accurate to within $1 / 4$ of $1 \%$ as measured on a precision laboratory bridge. A known Cx of $312.3 \mathrm{pF} \pm 1 / 4 \%$ produced a frequency shift of 497 kHz . If these values are substituted into equation (4), $C x$ is calculated to be 303.9 pF or 8.4 pF less than it should be.

This amounts to an error of $2.7 \%$ and is attributed directly to transistor loading shifting the oscillator frequency. Another way of looking at it is that the transistor has added 27.7 pF of capacitance to the tuned circuit. The term "transistor loading factor" is used somewhat loosely. It also includes the circuit stray capacitances. To allow for the loading effect a constant K1 is inserted into equation (4).
(6) $\mathrm{C}_{\mathrm{X}}=\mathrm{K}_{1} \mathrm{C}_{1}$

$$
\left(\frac{1}{1-\frac{2 \Delta \mathrm{f}}{\mathrm{f}_{1}}+\frac{\Delta \mathrm{f}^{2}}{\mathrm{f}_{1}^{2}}}-1\right)
$$

where $\mathrm{K}_{1}=1.02768$
The term A could have been calculated directly from the inductance and transistor parameters but it would have been for an "average" transistor. The question is "What is the variability in this term with different transistors in the circuit?" To answer this question quantities of different transistors were plugged into the circuit and the change in $\Delta \mathrm{f}$ was noted. Intermediate frequency type 2 N404's produced a variation of $\pm 6$ kHz shift out of 500 kHz . The high frequency type 2 N 964 produced a negligible variation in shift of $\pm 11 / 4 \mathrm{kHz}$ out of 500 kHz and were therefore judged the most satisfactory. The Motorola HEP 1 at 89 cents acts the same as the 2 N 964 and is recommended.

The average ham would hardly want to solve equation (6) every time he wanted to make a capacitance measurement and therefore a computerized solution was sought. With 1 KC increments in $\triangle \mathrm{f}$ being available and covering a 500 kHz range - 500 calculations have to be made. The computer is a natural tool for this job. The problem was programmed for a Univac 1107 and all 500 points were calculated in seven seconds. It would have taken me 41 hours with a desk calculator to get the same answers with many mistakes. The results are photographically reproduced in Fig. 2. Don't be fooled by all of the significant digits in the capacitance columns. Although the accuracy is inherently there, your answer is limited by the accuracy of C 1 and your receiver calibration.

## Circuit and Construction Details

TR1, L1, C1 of Fig. 3 form the Hartley Oscillator circuit. TR2 is a buffer amplifier driven from the emitter tap on L1. Its function is to isolate any loading on the

Fig. 3. Schematic. TR1,TR2: 2N964, HEP1; RFC: 2.5 MH National R100S; L1: 3/8" dia. slug tuned form, J.W.Miller 4400, 12 turns closewound No. 26 E , tap 3 turns from the bottom; CR1: 1N34 type germanium diode; C1: 1000 pF precision capacitor (see text); C5: 1000 pF mica; other capacitors can be ceramic or paper. All resistors $1 / 2 \mathrm{~W}, 10 \%$.
output of TR2 from affecting the oscillator frequency. CR1 is a safety diode that prevents the application of reversed voltage from causing any damage. The circuit is conventional in all other aspects.

The complete unit is built into a $5^{\prime \prime} \times 3^{\prime \prime} \times 2^{\prime \prime}$ minibox with plenty of space to spare. All components except L1, RFC, C2, C1 and the on-off switch are mounted on a $2-1 / 4^{\prime \prime} \times 1-7 / 8^{\prime \prime}$ piece of 85 G 24 EP Vectorboard (holes on . 1 inch centers staggered) and held onto the chassis by spade lugs. A layout of the board is shown in Fig. 4. The components are mounted by inserting the leads through the holes and crimping them as shown in Fig. 4. Although the components can wiggle when first installed, the board becomes one solid mass after wiring. Wiring is done on the back side of the board in

Inside view of device.

Method of crimping component lead.

conventional fashion. It is recommended that construction similar to that shown be followed in order to minimize the effect of stray capacitances on accuracy. $1 \%$ of 1000 pF is 10 pF which means that the $r f$ wiring must be short, direct and kept away from ground. For this latter reason, the hot end of L1 and C1 must be isolated from ground. This is accomplished by mounting the binding posts on a $2-1 / 8^{\prime \prime} \times 1-5 / 8^{\prime \prime}$ piece of phenolic and inserting behind a $1-13 / 16^{\prime \prime} \times 1-1 / 16^{\prime \prime}$ cutout on the top front of the aluminum box as shown in the photograph. The terminals are mounted $13 / 16^{\prime \prime}$ apart to conveniently accept the leads of the capacitor to be measured.

C3, the .02 disc ceramic bypass capacitor, mounts between the bottom end of L1 and the spade lug ground. TR2 output feeds to a phono type jack. Although there is sufficient space to include a 9 v battery inside the box, I decided to bring power in through a terminal strip instead. The chances are that the CMBFS unit will receive occasional use and that the battery will be dead when you do want to use it. I thought it best to use an external power supply or a battery borrowed from a transistor radio BC set when needed.

## Operation

Apply voltage to the CMBFS unit. Tune your receiver to 4000 kHz . Connect the output lead to the receiver antenna terminal. Tune L1 until the signal from the oscillator is zero beat with the receiver. It should be a
well over S9 stable signal. Now connect the capacitor to be measured to the binding posts. You will note that the signal is no longer at 4000 kHz . Tune your receiver lower in frequency until the new signal is picked up and zero beated. If there is any question about it being the correct signal, bring your finger near the hot binding post and the frequency will shift slightly. Record the new frequency and subtract it from 4000 kHz to get the shift $(\Delta \mathrm{f})$ in frequency. Now read the actual value of the capacitor corresponding to $\Delta \mathrm{f}$ directly from the chart (Fig. 2). That's about all there is to it.

It may not be necessary to actually connect the CMBFS unit output to the receiver antenna terminal. Radiation from a 2 or 3 foot piece of wire may be sufficient, depending upon the shielding of the receiver. More important is the elimination or reduction of 80 meter signals from other amateur stations that tend to confuse or lose the CMBFS signal. Disconnecting the 80M receiving antenna is desirable. I have found that switching to the 10 or 15 meter antenna or the dummy load is quite effective in reducing extraneous 80 M signals.

The battery voltage isn't critical. A 1 volt shift from -9 to -8 volts causes a barely discernible several cycles shift in frequency. Although the oscillator will oscillate down to 2 volts, I don't recommend operating at this point because the loading factor K1 will noticeably increase and cause an inaccuracy in the measurement.

## Summary

Equations - equations, the proof is in the performance! A number of capacitors were selected from the junk box, measured by this technique and compared to the $1 / 4 \%$ precision laboratory bridge. The receiver measurements were made with my old Collins 75A1 and repeated with a Drake TR3 transceiver. The results were as follows.

| Face | CMBFS | Precision Bridg Value |
| :---: | :---: | :---: |
| 10 pF | 10.35 pF | 10.45 pF |
| 50 pF | 50.8 pF | 51.6 pF |
| 100 pF | 115.2 pF | 115.0 pF |
| 180 pF | 175.0 pF | 174.6 pF |
| 270 pF | 269.36 pF | 268.4 pF |

Not bad, considering that the CMBFS unit costs less than $\$ 10$ while the precision bridge costs over $\$ 1,000$.

Although this particular unit has a capacitance range up to 313 pF , there is no reason why a higher C1/L ratio can't be chosen to permit reading higher values of capacitance, that is, if you have a computer handy to give you a new set of computations. Another approach for extending the range is to keep C 1 at 1000 pF , but split it into two parts with the unknown capacitor placed across one of the parts in a capacitive divider arrangement. This again requires recomputation. The present range satisfied the majority of my requirements in working with rf circuits and provided the excellent definition of $.5 \mathrm{pF} / \mathrm{kHz}$ at the low end and $.75 \mathrm{pF} / \mathrm{kHz}$ at the high end of the range. Thus this approach, coupled with the computer printout rather than the usual plotted curve, permits measuring a fraction of a pF difference between 300 pF capacitors.

CMBFS isn't a technique for the production line testing of capacitors but it is well suited for the occasional amateur need and is capable of providing a high degree of accuracy at low cost.
