

# DUKANE

## Installation and Service

### 125 WATT POWER AMPLIFIER

### MODEL 1A3125

#### GENERAL DESCRIPTION

The Dukane 125-Watt Power Amplifier, Model 1A3125, is designed for such applications as General Paging and Institutional Communication Systems. It requires 5-1/4" (13.3 cm) of vertical space in a standard 19" equipment rack on console.

When AC power is applied to the unit, a red LED (front panel) POWER indicator illuminates. The primary AC circuit is protected by a four ampere Slo-Blo fuse. Overheating of the output transistors will cause the temperature-controlled thermostat (fastened to the heatsink) to open the primary power circuit, illuminating a red LED (front panel) captioned THERMAL OVERLOAD. When temperature is reduced, the thermostat closes the AC power circuit, and the thermal overload indicator goes out.

#### INSTALLATION NOTES

The 125-Watt Power Amplifier provides full rated output with 1 volt input, single-ended.

It is good practice to ground the amplifier chassis to the rack or console metalware which is, in turn, connected to conduit and electrical system ground. To be certain grounding exists between the amplifier and the metalware, place an outside-toothed lockwasher under the head of one of the mounting screws.

Class II wiring is permissible for 25-volt and 70-volt level (speaker line). AC power wiring must be Class I wiring ONLY.

As with any electronic equipment, useful life will be extended by minimizing a units operating temperature. We recommend that any leftover rack space be used to separate the amplifiers from one another. The space may be filled with ventillated panels (order two 560-1232 (1-3/4" panel) or (order two 560-1234 (3-1/2" panel). Do not fill any rack to more than 2/3 of full capacity with amplifiers.

#### EXTERNAL CONNECTIONS

Make all external connections to screw terminals on the rear of the amplifier. Connect AC power to the amplifier AFTER external connections have been made and checked for short circuits.

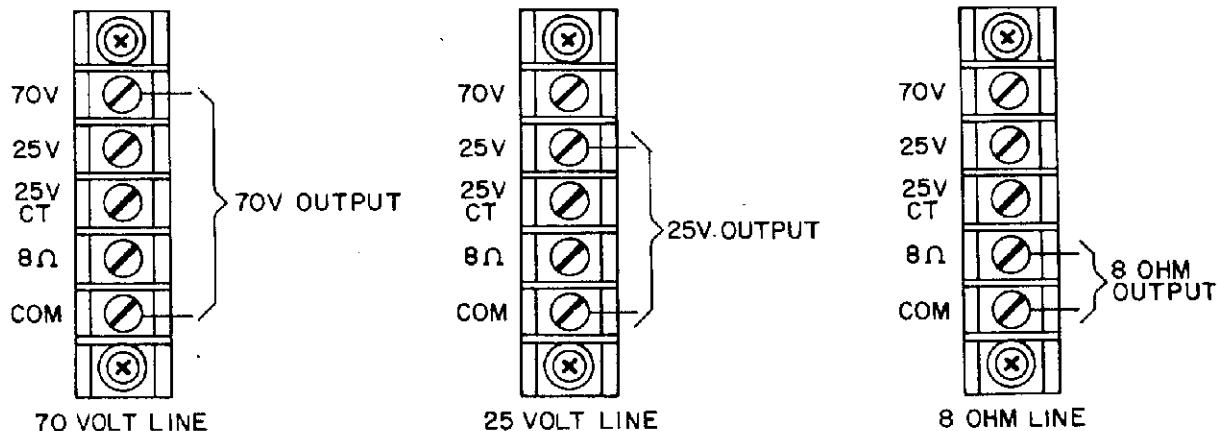

A conventional speaker system of up to 125 watts, including appropriate speaker-to-line matching transformers, can be connected to this amplifier.

403-351A

## OUTPUT CONNECTIONS

Connect speaker line as shown below.

When this amplifier is used in sound systems that include 25-volt intercom operation, connect the 25-volt center tap to the sound system ground to minimize crosstalk.

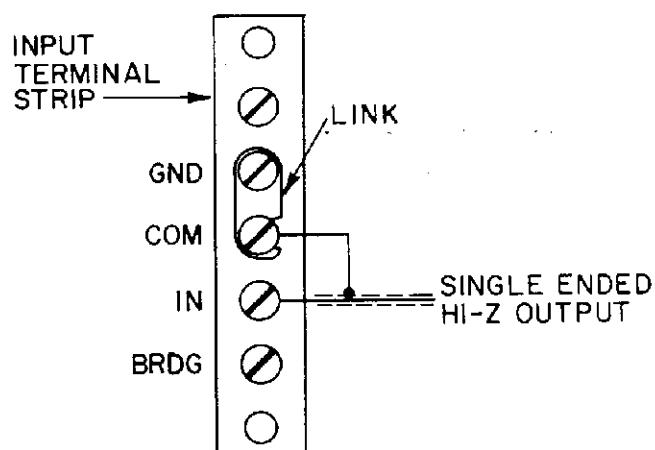

Note: If a 2.5-ohm load is connected from 25V CT (center tap) to "COM", the maximum output is 62 watts.

## INPUT LEVEL

Not more than 1 volt rms (sine wave) input is required to obtain full output power. However, it is recommended that, in order to accommodate the complex wave form of program material, the input should be lowered 8 dB for actual amplifier installation and operation. Hook up a voltmeter to either 25 volts or 70 volts output of the amplifier. Turn input level control (R101) to OFF (counterclockwise). Apply 700 Hz to 1 kHz sine wave at 1 volt at input of amplifier. Adjust input level control for a reading of 10 volts on 25-volt output, 28 volts on 70-volt output.

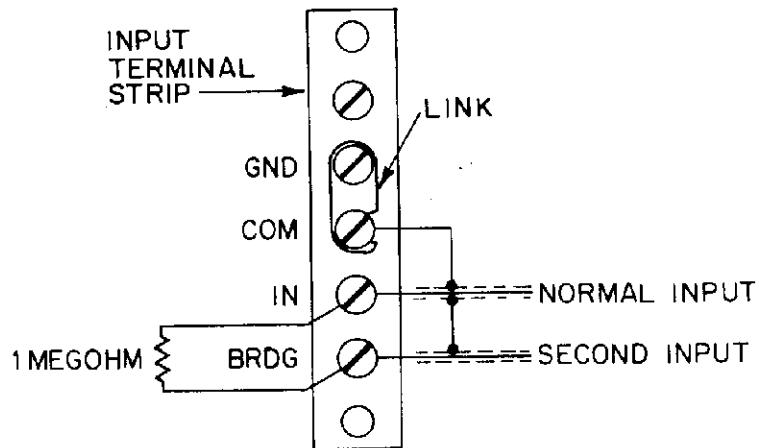

## INPUT CONNECTIONS

Input connections are made to screw terminals labeled "IN" and "COM" with shield to "COM" as shown below.

In some instances, to reduce any hum pickup, it may be desirable to disconnect the link between "COM" and "GND" on the input terminal strip.

If there is a second single-ended Hi-Z input to the amplifier, connect the second input to "BRDG" terminal and to shield and add a 1 megohm resistor between "IN" and "BRDG" as shown below. Another application for bridging input would be when it is required to operate multiple amplifiers from a single 600-ohm source.

#### AC POWER CONNECTIONS

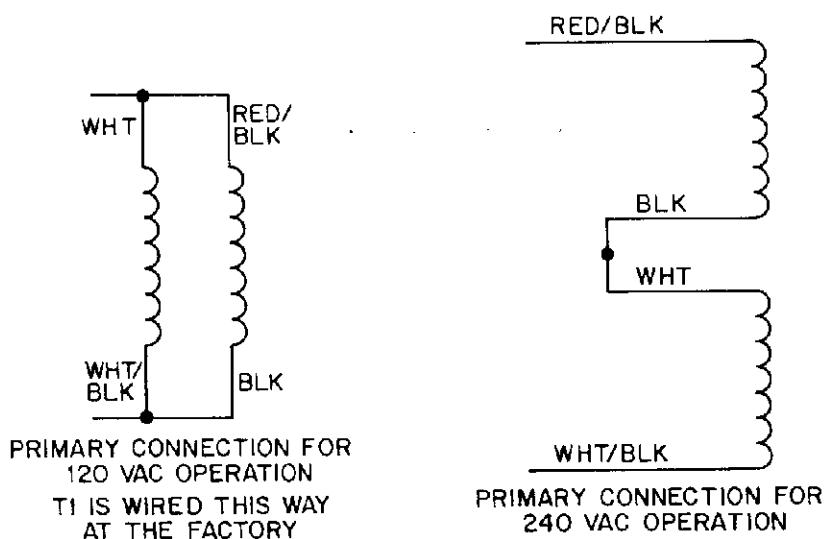

##### IMPORTANT

Before connecting AC power to this amplifier, BE CERTAIN that correct output load (speakers correctly matched to speaker line) and input connections are properly made to terminals of the amplifier.

AC power wiring MUST BE CLASS I WIRING ONLY.

The power transformer (T101) in the amplifier has two primary windings for 120 Vac operation. The primaries are wired in parallel as shown below on the left.

For 240 Vac operation, the two primaries in the amplifier must be wired in series as shown below on the right. For 240 Vac operation, the fuse (F101) must be halved in current capacity.

## **ASSOCIATED EQUIPMENT**

**Model 3A130 Input Transformer.** This is a one-to-one isolation input transformer. Its primary function is to isolate equipment and eliminate ground problems.

**Model 3A230 Bridging Transformer.** This transformer permits running multiple amplifiers from a single 600-ohm mixer output, providing all the benefits of isolation.

**Model 110-1188 Input Transformer Adaptor.** This consists of a transformer mounting bracket with a three contact terminal strip, an octal socket for receiving a plug-in input transformer, and a hole for an input level potentiometer shaft. See Installation Instructions #402-236.

560-1232. A pair of 1-3/4" ventilation panels.

560-1234. A pair of 3-1/2" ventilation panels.

SERVICE

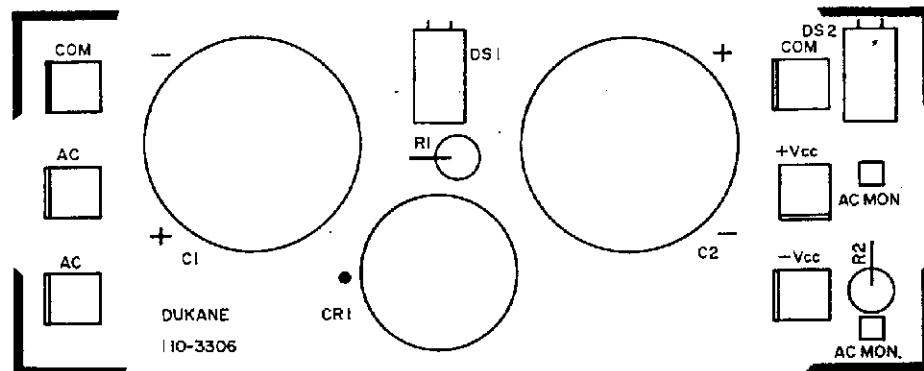

For Service Instruction Diagram see Drawing 400-1833 on Page 11.
