SPECIFICATIONS
GUIDE

LAKE ENGINEERING CO. LIMITED

123 MANVILLE RD. SCARBOROUGH ONTARIO

SUBMINIATURE LAMP SPECIFICATIONS GUIDE

LAKE subminiature lamps are designed to meet requirements for extremely small size, extra long life and low costs. Lamps are grouped in this Guide by bulb sizes and are listed according to design volts in ascending order within the size group. For easy reference the NUMERICAL INDEX at rear of this Guide lists the lamps in numerical sequence.

AGED AND SELECTED LAMPS

Where precise light output is of primary importance, Lake lamps are Aged and Selected. All T-3/4 and T-1 lamps are aged a minimum of 10 hours then individually measured for candlepower. T-1-1/4, T-1-1/2 and T-1-3/4 lamps are Aged and Selected to specific customer requirements.

BASE

The base provides electrical contact and support for the lamp. Unbased lamp leads are domet wire. T-3/4 and T-1 lamp leads are tin-plated for solderability.

BULB

The bulb is the glass envelope which houses the lamp filament assembly and contains the vacuum or gas. A letter and number identifies bulb shape and approximate bulb diameter in eighths of an inch.

CANDLEPOWER

Mean Spherical Candlepower (MSCP) is the value of a lamp's total integrated brightness as measured in a photometric sphere. This level depends on the lamps electrical parameters and the envelope size. All standard lamps are tested by photometers using lamp standards traceable to the National Bureau of Standards. (For conversion of MSCP to lumens, multiply the MSCP x 12.57.)

COLORED LAMPS

Signal and Specification colors are coated directly onto the glass bulb and are available on all based and unbased lamps listed in this catalog. Signal colors include amber, red, green and blue. Specification colors for Instrument lighting include red (MIL-L-25467) and blue-white (MIL-L-27160) for white light color correction. Color matching to customer requirement is also available.

DESIGN AMPERAGE

This is the actual current flowing through the filament at rated voltage.

DESIGN VOLTAGE

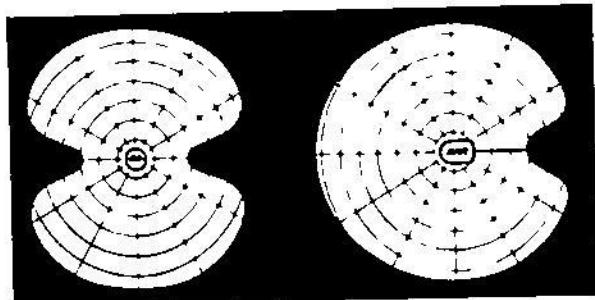

This is the operating voltage for which a lamp is designed. In certain cases, the industry has modified the original design voltage. For example, Type 328 was originally designed for 5.0 volts. Industry now rates it at 6.0 volts, but still calculates brightness at 5.0 volts. Obviously, this change in voltage rating also affects amperage and MSCP specifications at 6.0 volts. Over-rating and under-rating should be considered when special requirements are needed.

FILAMENT

The filament is the light emitting portion of the lamp. A prefix letter indicates whether the wire is straight (S), coiled (C) or coiled-coil (CC) and a number designates the geometric configuration of the filament support wires.

FILAMENT DISTRIBUTION

Consideration of filament orientation should not be overlooked to gain maximum efficiency from a lamp. The drawings below illustrate the output from an unsupported coil filament. Note that a reduction of light output occurs when one filament strand is hidden by the other. A reduction may also be noted in the area of the lead-in wires. Adding a base to a lamp will reduce the MSCP by approximately 10%.

FLASHING AND PULSATING

There is no noticeable sacrifice in the life of sub-miniature lamps used in flashing and pulsating lamp circuits as long as the inrush current is considered and light output does not exceed that of the steady burning position.

HEAT

Above 300°F, the solder on based lamps may soften and deform, the basing cement may loosen, evolved gas may attack the filament or the glass envelope may soften.

INRUSH CURRENT

The initial current through a cold filament which can be as much as 10 to 12 times greater than normal operating current. As resistance causes the filament temperature to rise, inrush current decreases. Inrush current can be reduced by using a low value of pre-heat voltage, and is an important consideration when lamps are to be used in a flashing or pulsating display.

LAMP IDENTIFICATION

Lamps are normally identified by an Industry Standard number issued and controlled by the United States American National Standards Institute (A.N.S.I.). Where a lamp has been designed for a special application it will use the original manufacturer's number until an A.N.S.I. has been assigned.

LAMP LIFE

Rated average life is that obtained in closely controlled laboratory testing of lamps on 60 Hertz alternating current at their design voltage. Very long life lamps are generally rated on the basis of extrapolated laboratory test data. Service conditions such as shock, vibration, voltage fluctuations, temperature, etc. may contribute to a shorter average life.

Ordinarily for still-rack operation, normal tungsten filament evaporation is the basic force or mechanism controlling incandescent lamp life. Where normal filament evaporation is the dominant failure mechanism, lamps should reach their design-predicted lifetimes.

In recent years another life-influencing lamp filament mechanism has become more prominent. This is commonly referred to as "filament notching". Its prominence is due to at least three factors, primarily associated with subminiature type lamps.

1. Low temperature filament operation, less than that for significant normal tungsten evaporation. (Long life lamp designs, such as 10,000, 25,000, 50,000 and 100,000 hour designs. This does not apply to filament temperatures below 1600°C.)
2. Small filament wire sizes, less than one mil (.001") diameter in many cases.
3. Increased use of D.C. voltage operation (generally resulting from advances in solid state technology.)

Notching is the appearance of step-like or sawtooth irregularities, appearing on all or part of the tungsten filament surface, after some burning. These notches reduce the filament wire diameter at various points. In some cases, especially in fine wire diameter lamps, the notching is so severe as to almost penetrate the entire wire diameter. Thus accelerated spot evaporation due to this notching (as well as reduced filament strength), now becomes the dominant mechanism for influencing lamp life. Because of its abnormal evaporation and/or reduced strength effects, lamp lifetimes due to notching may be one-half or less of so called ordinary or normal, predicted lamp lifetimes.

LAMP RERATING

Electrically, subminiature lamps are dynamic devices. Candlepower, current and life may be varied for all subminiature lamps by operating the lamps at other than design voltage. Rerating may be accomplished by the following formulae:

$$\text{RERATED M.S.C.P.} = \left(\frac{V}{V_1} \right)^{3.5} \times \text{M.S.C.P. AT DESIGN VOLTS}$$

$$\text{RERATED LIFE} = \left(\frac{V_1}{V} \right)^{12} \times \text{LIFE AT DESIGN VOLTS}$$

$$\text{RERATED CURRENT} = \left(\frac{V}{V_1} \right)^{-0.55} \times \text{CURRENT AT DESIGN VOLTS}$$

V = APPLICATION VOLTAGE

V₁ = DESIGN VOLTAGE

LAMP SPECIFICATIONS

At present there are Military Specifications covering a wide range of lamps. Although these specifications perform a valuable service to the industry, they are not rigid enough to guarantee a high quality lamp. Therefore, LAKE specifications may greatly exceed the Military Specification drawings.

At this time there is no QPL (Qualified Product List) for MIL Spec lamps, although one is currently being developed by the government. Therefore LAKE markets lamps to the applicable MIL Spec stating that they properly conform to design and manufacture.

SUBMINIATURE LAMP SPECIFICATIONS GUIDE

LIGHT CENTER LENGTH

Light center length is the average measurement for which the lamp is designed and is subject to nominal manufacturing tolerances. It is measured from the geometric center of the light source to a particular point of the base. This point is shown below for the base types used in sub-miniature lamps.

- | | |
|---------------|------------------------------|
| Bi-Pin | - Bottom of Base |
| Flanged | - Top of Flange |
| Grooved | - Center of groove |
| Screw | - End of bottom base contact |
| Wire Terminal | - Not specified |

MAXIMUM OVERALL LENGTH (MOL)

Maximum overall length is the largest total length which the lamp or the lamp and base will not exceed.

OPERATING TEMPERATURE

The glass used in making standard bulbs for miniature lamps will outgas when the surface temperature exceeds 300°F. Caution should be exercised to provide adequate heat removal through radiation, conduction and/or convection. The leads of a lamp provide a path for conducting heat. The mass of the terminal points where the lamp is connected should be adequate to provide a heat sink and the wiring leading from the connection points should be large enough to carry away this heat.

RISE TIME

By varying filament wire diameter, coil size and spacing as well as voltage and current, the rise time of a miniature lamp may be varied from 10 to 200 milliseconds from cold to operating brightness.

Modulation of a lamp filament is possible within certain design limits. The rise time may be accelerated by use of a wave form with a high voltage front phased in time to reduce to design level when the filament reaches design temperature.

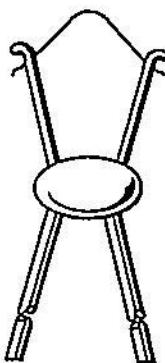

SHOCK AND VIBRATION

Miniature lamps vary greatly in their ability to operate under conditions of shock and vibration. The tensile strength of tungsten is 10 times greater when cold than when heated to operating temperature. This is to confirm that a lamp will withstand much higher shock and vibration non-operating than when operating.

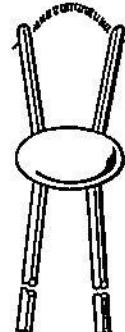

High current/low voltage filaments represent short length and large wire size as compared to low current/high voltage filaments and therefore will stand higher shock and vibration due to higher mechanical strength.

Lamps are tested to MIL Standard 202C-Method 202A for vibration and Method 202B for shock.
